The [Hospital Survey on Patient Safety Culture](#) and [Nursing Home Survey on Patient Safety Culture](#) were used in one Finish healthcare organization to assess 1) differences in employee perceptions of safety culture in their respective settings, and 2) differences between professionals' and managers' views. Managers assessed [safety culture](#) higher than professionals in both settings. Acute care patient safety scores were significantly positive in 8 out of twelve domains, compared to only one in long-term care.
